

Six Most Reported Health Conditions for High School Students (Data from SC Annual School Nursing Surveys)

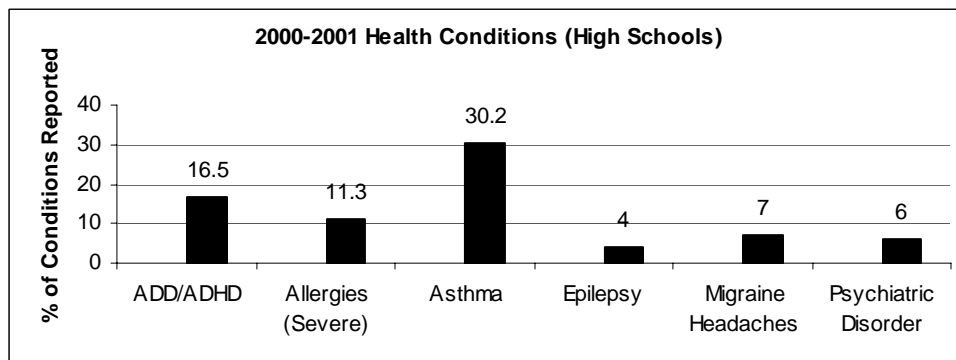

With the exception of the 2001-2002 school year, the six most reported health conditions for high school students has remained consistent over the past five school years (asthma, attention deficit disorder / attention deficit disorder with hyperactivity, severe allergies, epilepsy, migraine headaches and psychiatric disorders). During the 2001-2002 school year, substance abuse replaced severe allergies as one of the top six conditions reported. Note, however, that only 12 of 85 school districts completed the 2001-2002 SC Annual School Nursing Survey. Attention deficit / attention deficit disorder with hyperactivity was reported less often in high school students than for elementary and middle school students for each school year represented. The graphs below show the percentage for each of the six most reported health conditions. The percentages refer to a percentage of the total of all health conditions reported for high school students for the school year indicated.

Survey responses received from 41 of 85 school districts.

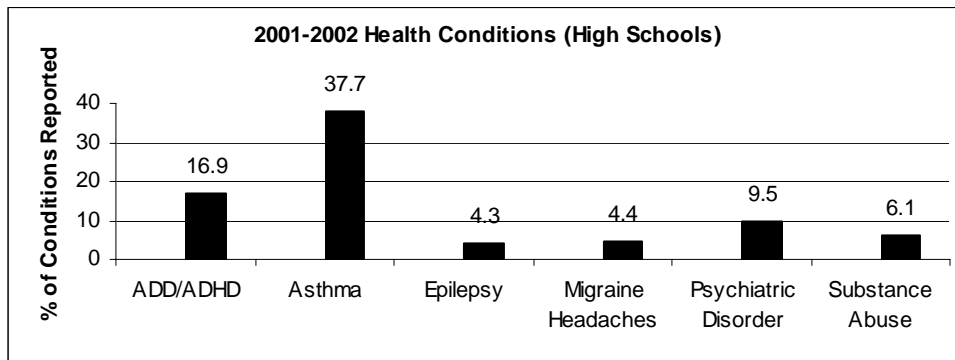

Survey responses received from 45 of 85 school districts.

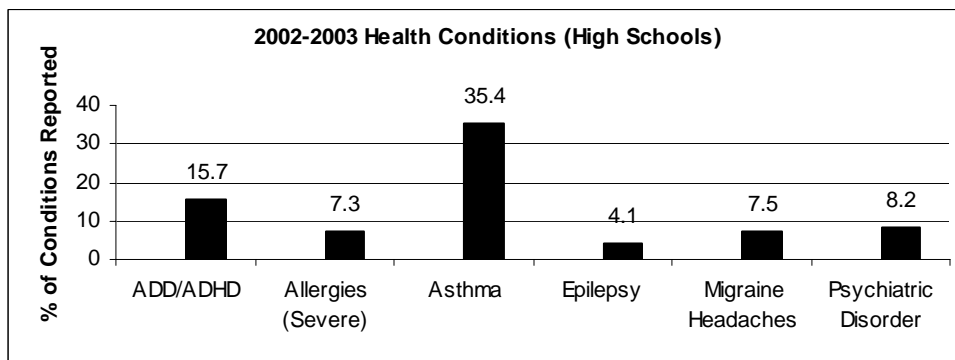

Survey responses received from 51 of 85 school districts.

Six Most Reported Health Conditions for High School Students (cont'd) (Data from SC Annual School Nursing Surveys)

Survey responses received from 12 of 85 school districts.

Survey responses received from 36 of 85 school districts.
